Milk and health, the facts at a glance
About this brochure

Milk contains essential nutrients including valuable proteins, vitamin B2 and B12 and minerals such as calcium. Milk and products made of milk fit into a healthy diet and are included in dietary guidelines throughout the world.

There are varying opinions and questions about the health of milk. Positive, but also critical such as: milk is for calves, milk can cause mucus production, milk is not necessarily good for our bones.

That is why the most frequently asked questions about milk and health are answered in this brochure based on science and nutritional guidelines.

Content

Does milk fit in a healthy diet? 4
Does skimmed milk contain fewer nutrients than full fat milk? 8
Will milk make you gain weight? 10
Adults do not continue to grow so do adults need calcium? 12
What is the role of milk in keeping strong bones? 14
Is a calcium supplement a good alternative to drinking milk? 16
What are the nutritional differences between soy drink and milk? 18
Does drinking milk stimulate the production of mucus in the mouth? 21
Do you get acne by drinking milk? 22
Can people with lactose intolerance consume milk and products made of milk? 24
Can children outgrow an allergy to cow’s milk protein? 26
Does drinking milk have an effect on the acid-base balance of the body? 28
Does drinking milk have an effect on the health of the heart and blood vessels? 30
Should people drink cows’ milk, isn’t it meant for calves? 32
What is the true story behind antibiotics and milk? 34
Food Based Dietary Guidelines are guidelines for a healthy diet and are being formulated to prevent nutrient deficiencies. In addition, they have increasing attention for the prevention of chronic non-communicable diseases. The dietary guidelines from different countries contain similar broad messages based on principles of nutritional science (such as eating enough fruit and vegetables). However, national dietary guidelines often contain unique features based on that country’s priorities and cultural habits. In most dietary guidelines, the recommended amount of milk and dairy products, such as yoghurt and cheese, is 2-3 portions per day.

**TABLE Dairy recommendation in dietary guidelines**

Not all countries have published their own dietary guidelines, and often use the dietary guidelines compiled by the USA. The FAO website gives an overview of dietary guidelines worldwide. Please find a summary below.

**Does milk fit in a healthy diet?**

Milk and milk products are included in many dietary guidelines worldwide. From Europe to Asia and from Africa to the Americas, milk is regarded as an important food at all life stages, from the very young to the elderly. This becomes apparent when looking at food based dietary guidelines more closely. In general, gender and age-specific guidelines are used. Milk provides various essential nutrients: valuable proteins, vitamin B2 and B12 and minerals such as calcium, phosphorus and potassium.

Based on:
FAO: overview worldwide dietary guidelines:
Milk and health, the facts at a glance

Skimmed or fat-free milk is milk where most fat has been removed resulting in a lower calorie content. Full fat milk contains 3-4% of fat, semi-skimmed or low-fat milk contains around 1.5% fat, and skimmed or fat-free milk contains less than 0.5% fat.

Most nutrients are in the non-fat portion of the milk and will not be affected by skimming the milk. Both full fat, semi-skimmed, and skimmed milk contain comparable amounts of high quality proteins, vitamin B2 and B12 and minerals, such as calcium, phosphorus and potassium. Milk fat, however, contains vitamin A and therefore the level of this vitamin will decrease without the fat from 8.8% RDA in whole milk to 0.3% RDA in skimmed milk.

| TABLE Nutritional value of skimmed, semi-skimmed and full fat milk per 200 ml glass: |
|-----------------------------------------------|-----------------------------------------------|-----------------------------------------------|
| Full fat milk | Semi-skimmed milk | Skimmed milk |
| per 200 ml %RDA* | per 200 ml % RDA* | per 200 ml %RDA* |
| Energy kJ/kcal | 511/122 | 385/92 | 293/70 |
| Fat g | 6.8 | 3 | 0.2 |
| Carbohydrates g | 9 | 9.2 | 9.8 |
| Protein g | 6.6 | 6.8 | 7.4 |
| Salt g | 0.22 | 0.21 | 0.22 |
| Vit B2 mg | 0.36 | 0.36 | 0.36 |
| Vit B12 mcg | 0.78 | 0.88 | 0.86 |
| Potassium mg | 330 | 324 | 254 |
| Calcium mg | 246 | 244 | 254 |
| Phosphorus mg | 204 | 204 | 212 |

* Recommendations are based on the EU Regulation 1169/2011 on Food Information to Consumers. Source: Nevo 2011

Does skimmed milk contain fewer nutrients than full fat milk?

The main difference between full fat milk and skimmed milk is the fat content and therefore the calorie content. The level of the most important essential nutrients in milk is independent of the fat content, and equal in both types of milk.

The vitamin A level is below 15% RDA/200 ml and is therefore not required to be included on packaging in the EU. In some countries milk is fortified with fat-soluble vitamin A and/or D. In that case the levels of vitamin A and D are independent of the fat level of the milk product.
Milk and health, the facts at a glance

Research shows that low-fat milk and products made of milk may even play a positive role in weight management. Recent meta-analyses of randomized controlled clinical trials prove that the consumption of dairy products in calorie controlled diets may have modest benefits in facilitating weight loss, and favourable changes in body composition. Along the same lines, a recent systematic review concluded that it appears dairy products have a preventative effect on the risk of becoming overweight or obese. Dairy products used regularly over a period of several years, make a small but significant difference to overall public health. None of the existing meta-analyses or review studies have indicated that dairy products, as part of a calorie controlled diet or not, could lead to an increase in body weight or fat mass.

Dietary guidelines worldwide recommend the intake of 2-3 portions of dairy produce per day as a part of a balanced diet. One glass (200 ml) of semi-skimmed milk provides about 90 kcal (may vary slightly from country to country) which is 5% of the average daily energy requirement. And milk also provides essential nutrients important for many bodily functions.

Will milk make you gain weight?

People who eat and drink more than the energy they expend will gain weight, no matter what they eat or drink. It is recommended to use lower calorie dairy products for weight management. Often, these products have a low-fat content and no added sugar. Some people think milk is fattening. Science does not endorse this.

Based on:

Will milk make you gain weight?

People who eat and drink more than the energy they expend will gain weight, no matter what they eat or drink. It is recommended to use lower calorie dairy products for weight management. Often, these products have a low-fat content and no added sugar. Some people think milk is fattening. Science does not endorse this.
Calcium is the most abundant mineral in bones and is an essential nutrient at all stages of life. As bone is a living tissue, constantly regenerated by being broken down and rebuilt. Therefore, an adequate intake of calcium is important for people at all ages. Calcium is essential for bone development in children and adolescents. As peak bone mass is reached at about the age of 25-30 years, optimal calcium intake is important in early adulthood. Calcium appears to be equally important throughout life as it not only contributes to the development of strong bones, but also to their continuing maintenance of bone mass, bone strength and bone mineral density (BMD). According to the recommendations from various scientific bodies worldwide, the highest levels of calcium intake are needed during adolescence and old age (see table).

Milk and milk products are an integral part of a healthy, balanced diet for all ages and are a good source of calcium. One glass of milk (200 ml) delivers approximately 30% of the recommended daily amount of calcium.

| TABLE Calcium intake recommendations (mg/day) from various scientific bodies |
|-----------------------------|-----------------|----------------|----------------|----------------|----------------|----------------|----------------|

Adults do not continue to grow so do adults need calcium?

Calcium is the most abundant mineral in the human body. There is increasing scientific evidence substantiating the need for adequate calcium intake throughout life, from the young to the elderly. Calcium not only supports growth in children, but is also important for optimal bone health in all age groups. Milk and products made of milk are a good source of calcium.
Bones consist of a matrix of protein, filled with calcium phosphate and other minerals such as sodium, magnesium, potassium and zinc. Throughout our lives bone tissue is continually broken down (resorption) and rebuilt (formation). This occurs partly for recovery from minor ‘damage’ and to adjust the density of the load-level on the bone. From birth until about the age of 30, bone formation exceeds bone resorption and bone density increases, leading to a peak bone mass (PBM). From the age of about 50, peak bone mass diminishes. The higher the PBM, the stronger the bones later in life.

The peak bone mass is mainly determined by genetics. There are some factors you can influence yourself, including healthy diet, sufficient exercise, no smoking, moderate alcohol intake. In addition, the use of certain medications influence bone density. Protein, calcium, vitamin D and physical bone load are the main factors contributing to good bone health. This applies particularly in puberty when bones are growing fast and 25-50% of the peak bone mass is developed. Consuming enough of these nutrients and exercising are also important at a later age to maintain bone strength.

Around a decade ago a number of scientific publications stated that increased protein intake may have an adverse effect on bone health as a result of an increased amount of calcium in the urine (hypercalciuria) and a decline of calcium in the bones. However, this is not confirmed by more recent scientific research. Only in the event of a very high protein intake, in combination with a low calcium intake, could there be an adverse effect on bone health. This is virtually eliminated if milk and products made of milk are part of your diet. It is also accepted that excessive consumption of caffeine, carbonated drinks, alcohol and salt can have an adverse effect on the calcium balance.

Milk is an important source of protein, calcium and phosphorous and therefore complements a diet that contributes to healthy bones. For people with low vitamin D-intake, milk enriched with vitamin D is advisable.

Based on:

What is the role of milk in keeping strong bones?

Heredity is the main factor in having strong bones. It determines 60-80% of the peak bone mass, the maximum bone density. Factors such as diet and exercise also play an important role in bone development during growth, and in the preservation of bone tissue in adults and the elderly. Calcium and protein derived from foods including milk and products made of milk are important for development and maintenance of bones.
Studies on calcium supplementation show low compliance in taking the supplements. This is possibly related to the size of calcium tablets and the gastrointestinal side effects associated with their use. People not eating a balanced diet could mistakenly believe that calcium tablets or supplements can serve as a substitute for a balanced diet and healthy lifestyle.

Milk or products made of milk can easily be included in our daily diet. One portion (200 ml) of milk provides around 30% of the daily recommended amount of calcium. Calcium is important for building and maintaining bones and teeth. Other nutrients, such as phosphorus and protein, are also important for bone health. Milk and products made of milk are another good source of these nutrients as well as of vitamin B2 and B12.

Based on:
4. NEVO: Netherlands Food Table; nevo-online.rivm.nl.
5. EU Regulation 1169/2011 on Food Information to Consumers

Is a calcium supplement a good alternative to drinking milk?

Milk provides a variety of essential nutrients such as protein, vitamin B2 and B12 and minerals including calcium, phosphorus and potassium. Therefore, milk provides much more than calcium. Calcium supplements may be seen as an addition to the amount of calcium that is obtained from food, but not as an adequate replacement for milk and products made from milk.

1 One portion (200 ml) of pasteurised semi-skimmed milk provides the following percentages of the recommended daily amount (RDA) of nutrients: Protein: 14%. Calcium: 30%. Phosphorus: 29%. Vitamin B2: 26%. Vitamin B12: 35%. Source: Nevo 2011.
What are the nutritional differences between soy drink and milk?

Milk and soy drink are often compared with one another, but are in fact very different products in terms of origin, taste and nutritional value. Milk is a product that naturally contains important essential nutrients: protein rich in essential amino acids and vitamin B2, vitamin B12, calcium, phosphorus, and potassium. Soy drink is made from soybeans (often from South America), and is a source of protein and magnesium. Many soy drinks are fortified with calcium and vitamin B2 and B12, making their nutritional value closer to that of milk. Both milk and soy drink can contribute to a healthy diet, but there are clear differences between the two products.

The quality of dietary protein depends on the digestibility of the protein and the level of essential amino acids in proportion to the amino acid requirement. While the protein quality of soy drink is good, milk protein contains more essential amino acids and is therefore of better quality. The digestibility of milk protein is also higher. According to a 2013 report from the FAO detailing a new method of determining protein quality (known as the DIAAS method), milk protein scores 10%-30% higher than the highest quality soy protein isolate.

Meanwhile, two-thirds of the fat in milk is saturated, while for soy the proportion is only 15%. To achieve a healthy cholesterol level and thus maintain a healthy cardiovascular system, it is recommended that saturated fats be replaced with unsaturated fats. But milk consists of more than just saturated fat. Recent scientific research suggests that normal consumption of milk and milk products has a neutral effect on cardiovascular health. So the relationship between milk and cardiovascular health appears to be more subtle than previously thought. Even though certain components of soy (lecithin and isoflavones) are sometimes linked to cholesterol reduction, the European Food Safety Authority (EFSA) considers the evidence insufficient.

There are also differences in terms of micronutrients. Milk is inherently rich in calcium and vitamin B12, and is a source of vitamin B2, phosphorus, and potassium. Soy has a different micronutrient profile, and is a source of magnesium. Because soy drink is often used to replace cow’s milk, many manufacturers add nutrients to soy drinks. Their specific choices differ across countries. In the Netherlands, soy drink is often fortified with calcium and vitamin B2 and B12—in the US, with calcium and vitamin A and D. Figure 1 provides an overview of how the various micronutrients from semi-skimmed milk and (unfortified) soy drink contribute to the recommended nutritional intake (%DRI per 200ml glass).

Although both milk and soy drink can contribute to a healthy diet, they differ in terms of their nutritional aspects. Health authorities worldwide recommend a daily consumption of 2-3 servings of milk and milk products. Two glasses of pasteurised milk (400ml) contribute 15%-70% of the daily recommended intake of protein, vitamin B2, B5, B8, B12, calcium, phosphorus, potassium, zinc and iodine.
Some people think there is a link between drinking milk and increased mucus production in the mouth. They believe milk should be removed from their diet and stop drinking it. The thin layer temporarily formed in the mouth by milk is often mistaken for increased mucus production. Scientific studies of milk and mucus production do not support an association between the two. Even in volunteers with a cold, drinking milk had no effect on mucus production.

Based on:
1. Wüthrich et al Milk consumption does not lead to mucus production or occurrence of asthma. Journal of the American College of Nutrition, 2005 Vol. 24, No. 6, 547S-555S.

Does drinking milk stimulate the production of mucus in the mouth?

There is no scientific evidence for a link between drinking milk and increased mucus production. Milk and foods with a similar ‘mouth feel’, such as drinks containing soy, briefly coat the mouth and throat. This milky coating only lasts a very short time. This is not the same as mucus production.
Acne is a skin condition characterised by numerous red inflamed pimples. The pimples are caused by the hormone testosterone, which provokes the glands in the skin to produce sebum. When there is excessive sebum production pores in the skin fill with sebum, bacteria, and dead cells, resulting in the formation of a pimple.

The cause of acne appears to be in factors such as skin type, genetics, hormones and environmental pollutants. There is no scientific evidence for the influence of a particular dietary pattern or a specific nutrient on the formation of acne or acne becoming worse.

According to the Dutch Association for Dermatology and Venereology (Nederlandse Vereniging voor Dermatologie en Venereologie) it is not justified to recommend - or restrict - certain foods for people with acne. On their website www.huidartsinfo.nl is stated that acne is not caused by eating certain foods. Especially pork, chocolate and chips are considered to be the culprits. Scientific research did not establish this connection. Also food allergies do not have influence on acne. The Association indicates that well-designed elimination studies are needed for proper recommendations about acne and nutrition. This indicates that there is no reason to discourage the use of milk or products made of milk for people with acne.

Based on:
4. American Academy of Dermatology (http://www.aad.org/skin-conditions/dermatology-a-to-z/acne)
5. www.huidartsinfo.nl

---

Do you get acne by drinking milk?

Some people believe consuming milk and products made of milk contribute to the development and severity of pimples and acne. However, scientific research on the relationship between milk and acne provides no conclusive evidence of a correlation between diet and acne.
Lactose intolerance occurs in around two-thirds of the world population. We speak of lactose intolerance when children aged over five years are less able to digest lactose, due to decreased levels of the enzyme lactase in the intestine. Because of the inadequate levels of the enzyme lactase, high amounts of lactose are present in the colon of people with lactose intolerance. The bacteria present in the large intestine ferment the lactose causing gas production, which may cause discomfort.

The one-third of the world simply can tolerate lactose. They have an adaptation in a gene that ensures the enzyme lactase is produced at high levels beyond childhood.

The treatment of lactose intolerance consists of omitting lactose from the diet. Usually, it is not necessary to eat completely lactose-free food. Small amounts of lactose usually cause no discomfort and are not harmful. Although some people do have complaints with an intake of less than 6 g of lactose most people with diagnosed lactose intolerance can digest about 12 g of lactose per day (about 250 ml of milk) with little to no symptoms. This is especially so if consumption is spread throughout the day, taken with meals and using products with a low lactose content. Yoghurt is another option as it has lower lactose levels, and hard cheeses, which contain hardly any lactose. Soft cheeses do contain lactose. Lactose free milk is available in most supermarkets. Given these options, even people with lactose intolerance can benefit from the essential nutrients provided by milk and products made of milk as part of their diet.

Based on:

Can people with lactose intolerance consume milk and products made of milk?

Part of the world’s population can not digest lactose. This is called lactose intolerance. People with lactose intolerance can tolerate around 12g of lactose per day. This is about 250 ml milk. In addition, semi-hard cheeses hardly contain lactose, and can therefore be eaten.
Can children outgrow an allergy to cow's milk protein?

Cow’s Milk Protein Allergy (CMPA) is defined as an undesirable reaction to the milk protein caused by an abnormal reaction in the body’s immune system. Its prevalence ranges between 2% and 7% in babies and toddlers, and decreases into adulthood to a prevalence of 0.1 - 0.5%. Although it is often said that more and more young children are becoming allergic to cow’s milk protein, there is no scientific evidence to support this and its prevalence seems to be generally overestimated.

Based on:
According to the underlying theory of acid-based balance, proteins in the diet, as well as phosphates, make the blood more acidic. The result of a slightly lower acidity (in more acidic blood) results from calcium being drawn from the bones as the body attempts to neutralise the blood. The theory behind this is based on more calcium found in acidic urine after drinking milk. Alkaline dietary patterns, for example those high in vegetables and fruit, are said to help decrease the acidity and to make the body less ‘acid’.

Although a higher protein intake does lead to a higher acid level in the urine, and more calcium excretion via the urine, this has no effect on the overall calcium balance in the body: that is, the difference between dietary intake of calcium and its excretion via urine and faeces. With a higher protein intake, the body absorbs more calcium from food. Similarly, increased phosphates in the diet do not affect the calcium balance. A diet with sufficient protein helps to preserve bones. The scientific panel of the European Food Safety Authority (EFSA) concluded, on the basis of the overall scientific research, that there is a cause and effect relationship between the intake of protein, phosphorus and calcium, and the preservation of bones.

Based on:

Does drinking milk have an effect on the acid-base balance of the body?

It is sometimes suggested that the modern Western diet, protein-rich and with products containing phosphates, has an acidifying effect on the body. Milk is often mentioned as one of those products. However, science shows that milk does not have an negative effect on the calcium balance in the body. The presence of protein, phosphorus and calcium even helps with the maintenance of the bones.
All over the world milk and products made from milk are incorporated in dietary recommendations. Milk-fat is two-thirds saturated fat. Replacing saturated fat in the diet by unsaturated fat is recommended for a healthy cholesterol level and thus maintaining a healthy heart and blood vessels.

Milk, however, consists of more than saturated fat. Recent scientific research indicates that a regular intake of milk and milk products has a neutral effect on the health of heart and blood vessels. Because of this, the relationship between milk and products made from milk, and health of heart and blood vessels seems to be more complex than previously assumed.

FrieslandCampina follows the official advice from authorities in health and nutrition and offers a wide range of milk and products made from milk with varying fat contents, so consumers can choose the best option for them.

Based on:

Does drinking milk have an effect on the health of the hearth and blood vessels?

To maintain a healthy heart and blood vessels, the World Health Organization advises consumers to use mainly skimmed or semi-skimmed (half fat) milk or products made from milk. The relationship between milk, and products made from milk, and health of heart and blood vessels seems to be more complex than previously assumed.
Just as humans discovered that grains are edible, and eggs contain useful nutrients, humans discovered milk is very nutritious too. Cows are ruminants and are able to convert grass, which cannot be digested by humans, into milk: a valuable source of indispensable, essential nutrients.

Based on:

Should people drink cows' milk, isn't it meant for calves?

Milk is meant for calves, but it can be used by humans. As long as 6,000 - 10,000 years ago, people kept cows, goats and sheep for their milk. Milk is a valuable source of vital, essential nutrients including protein, vitamin B2 and B12 and minerals including calcium, phosphorus and potassium. Consuming milk or products made of milk can be a tasty way to take these nutrients.
Antibiotics are medication used to prevent and combat infections in humans and animals. For example, farmers use antibiotics to treat udder infections. As antibiotics are not allowed in milk or products made of milk, cows treated with antibiotics are milked separately from the rest of the herd for a specific period of time, usually between 3-7 days. This milk is not processed.

There are several control points in the dairy chain at FrieslandCampina:

- Member dairy farmers are obliged to keep a drug register, which is checked by an independent third party.
- Each tank of milk is tested for the presence of antibiotics before the milk is transported to the factory.
- Whenever FrieslandCampina uses and buys raw milk, the milk is always tested before it reaches the factory.

Based on:
1. FIDIN: Fabrikanten en Importeurs van diergeneesmiddelen in Nederland: http://repertoriumonline.fidin.nl
2. VWA: http://www.vwa.nl/onderwerpen/levensmiddelen-food/dossier/zuivel/wat-is-er-geregeld

What is the true story behind antibiotics and milk?

Antibiotics do not belong in milk and there are strict controls in the use of antibiotics in stock farming. FrieslandCampina has strict procedures to ensure there are no antibiotics in its milk and products made of milk.
